Streams and File I/O

Streams

- Aaahhh... a delicious stream of sushi...

    (on conveyor belt)

- One at a time
- Input to your belly

Streams

- Aaahhh… a delicious stream of sushi…

    (on conveyor belt)

- One at a time

- Input to your belly

- Eventually, no more sushi

    (restaurant closes)

Reading and Writing Files

- The C++ input/output library is based on the concept of *streams*.
- An *input stream* is a source of data.
- An *output stream* is a destination for data.

- The most common sources and destinations for data are the files on your hard disk.
  - You need to know how to read/write disk files to work with large amounts of data that are common in business, administrative, graphics, audio, and science/math programs

Streams

This is a stream of characters. It could be from the keyboard or from a file. Each of these is just a character - even these: 3 -23.73 which, when input, can be converted to: ints or doubles or whatever type you like.
(that was a '\n' at the end of the last line)
&*@&^#!%#$ (No, that was -not- a curse!!!!!!!!!!
¥1,0000,0000 (price of a cup of coffee in Tokyo)
Notice that all of this text is very plain - No bold or green of italics - just characters - and whitespace (TABs, NEWLINES and, of course... the other one you can't see: the space character:
(another '\n')
(&& another)

Streams

whitespace (TABs, NEWLINES and, of course... the
other one you can't see: the space character:
 (another '\n')
 (&& another)   (more whitespace) and FINALLY:**

Reading and Writing Streams

- The stream you just saw is a plain text file.

- No formatting, no colors, no video or music (or sound effects).

- A program can read these sorts of plain text streams of characters from the keyboard, as has been done so far with `cin`.

Reading and Writing Disk Files

You can also read and write files stored on your hard disk:

- plain text files
- binary information (a binary file)
  - Such as images or audio recording

To read/write files, you use *variables* of the stream types:

> `ifstream` for input from plain text files.
> `ofstream` for output to plain text files.
> `fstream` for input and output from binary files.

You must `#include <fstream>`

Opening a Stream

- To read anything from a file stream, you need to *open* the stream. (The same for writing.)
- *Opening a stream* means associating your stream variable with the disk file.
- The first step in opening a file is having the stream variable ready.

Opening a Stream

- To read anything from a file stream, you need to *open* the stream. (The same for writing.)
- *Opening a stream* means associating your stream variable with the disk file.
- The first step in opening a file is having the stream variable ready.

Here's the definition of an input stream variable named **in_file**:

ifstream in_file;

Looks suspiciously like every other variable definition you've done
– it is!
Only the type name is new to you.

Code for opening a stream

```
ifstream in_file;
in_file.open("input.txt"); //filename is input.txt
```

An alternative shorthand syntax combines the 2 statements:

```
ifstream in_file("input.txt");
```

- As your program runs and tries to find this file, it WILL ONLY LOOK IN THE DIRECTORY (FOLDER) IT IS LOCATED IN!

- This is a common source of errors. If the desired file is not in the executing program's folder, the full file path must be specified.

File Path Names

File names can contain directory path information, such as:

UNIX
```
  in_file.open("~/nicework/input.dat");
```

Windows
```
  in_file.open("c:\\nicework\\input.dat");
```

When you specify the file name as a string literal, and the name contains backslash characters (as in Windows), you must **supply each backslash _twice_** to avoid having unintended _escape characters_ in the string.

 \\ becomes a single \ when processed by the compiler.

Failing to open

- The **open** method also sets a "not failed" condition
- It is a good idea to test for failure immediately:

```
in_file.open(filename);

// Check for failure after opening
if (in_file.fail())                    if(!in_file.is_open())
{                                      {
    return 0;            or                return 0;
}                                      }
```

Closing a Stream

- When the program ends, all streams that you have opened will be automatically closed.
- You *can* manually close a stream with the **close** member function:

```
in_file.close();
```

1. Create variable
2. Open file (provide filename)
3. Check if file opened successfully
4. Read from file
5. Close file

SLAM!

Reading from a stream

If you have the following stored in a file:

```
Supriya 534
```

You already know how to read and write using files.

Yes you do:

```
string name;
```

```
double value;
```

Reading from a stream

If you have the following stored in a file:

```
    Supriya 534
```

You already know how to read and write using files.

Yes you do:

```
string name;
double value;
in_file >> name >> value;
```

Reading from a stream

You already know how to read and write using files.

Yes you do:

```
string name;
double value;
in_file >> name >> value;
```

cin? **in_file**?

No difference when it comes to reading using **>>**.

Reading from a stream

- The **>>** operator returns a "not failed" condition, allowing you to combine an input statement and a test.
- A "failed" read yields a **false** and a "not failed" read yields a **true**.

```
if (in_file >> name >> value)
{
    // Process input
}
```

Reading from a stream

- You can even read ALL the data from a file because running out of things to read causes that same "failed state" test to be returned:

```
while (in_file >> name >> value)
{
    // Process input
}
```

Reading A Whole Line: `getline`

- The function **`getline()`** reads a whole line up to the next '\n', into a C++ string.

- The '\n' is then deleted, and NOT saved into the string.

```
string line;
ifstream in_file("myfile.txt");

getline(in_file, line);
```

Reading A Whole Line in a Loop: `getline`

- The **getline** function, like the others we've seen, returns the "not failed" condition.

- To process a whole file line by line:

```
string line;
while( getline(in_file, line)) //reads whole file
{
    // Process line
}
```

Functions in `<cctype>` (Handy for Lookahead)

Function	Accepted Characters
isdigit	0 … 9
isalpha	a … z, A … Z
islower	a … z
isupper	A … Z
isalnum	a … z, A … Z, 0 … 9
isspace	White space (space, tab, newline, and the rarely used carriage return, form feed, and vertical tab)

Reading Words and Characters

What really happens when reading a `string`?
```
string word;
in_file >> word;
```

1. Any whitespace is skipped
   (whitespace is: `'\t'` `'\n'` `' '`).

2. The first character that is not white space is added to the string `word`. More characters are added until either another white space character occurs, or the end of the file has been reached.

Reading Words and Characters

You can read a single character, including whitespace, using `get()`:

```
char ch;
in_file.get(ch);
```

The `get` method returns the "not failed" condition so:

```
//reads entire file, char by char
while (in_file.get(ch))
{
    // Process the character ch
}
```

Reading a Number Only If It Is a Number

- You can look at a character after reading it and then put it back.
- This is called *one-character lookahead*. A typical usage: check for numbers before reading them so that a failed read won't happen:

```
char ch;
int n=0; //for reading an entire int
in_file.get(ch);

if (isdigit(ch)) // Is this a number?
{
    // Put the digit back so that it will be part of the number we read
    in_file.unget();

    in_file >> n; // Read integer starting with ch

}
```

Writing to a Stream

Here's everything:
1. create output stream variable
2. open the file
3. write to file
4. close file!

```
ofstream out_file;
out_file.open("output.txt");
if (in_file.fail()) { return 0; }
out_file << name << " " << value << endl;
out_file << "CONGRATULATIONS!!!" << endl;
```

Working with File Streams

SYNTAX 8.1 Working with File Streams

Include this header when you use file streams. ———— `#include <fstream>`

Use `ifstream` for input, `ofstream` for output, `fstream` for both input and output.

```
ifstream in_file;
in_file.open(filename.c_str());
in_file >> name >> value;
```

Call `c_str` if the file name is a C++ string.

Use the same operations as with `cin`.

```
ofstream out_file;
out_file.open("c:\\output.txt");
out_file << name << " " << value << endl;
```

Use \\ for each backslash in a string literal.

Use the same operations as with `cout`.

When the File Name is in a C++ string variable

- If the filename comes from the user, you will store it in a string.

- If you use a C++ string, some older library versions require you to convert it to a C-string using `c_str()` as the argument to open():

```
cout << "Please enter the file name:";
string filename;
cin >> filename;
ifstream in_file;
in_file.open(filename.c_str());
```

Opening a Stream, Filename is a `char[]` array

```
cout << "Please enter the file name:";
char filename[80];
cin >> filename;
ifstream in_file;
in_file.open(filename);
```
